

Python Programming

1: Design a Python application that creates two threads named Prime and NonPrime.

- Both threads should accept a list of integers.
- The **Prime** thread should display all prime numbers from the list.
- The **NonPrime** thread should display all non-prime numbers from the list.

2: Design a Python application that creates two threads.

- Thread 1 should calculate and display the **maximum element** from an list.
- Thread 2 should calculate and display the **minimum element** from the same list.
- The list should be accepted from the user.

3: Design a Python application where **multiple threads update a shared variable**.

- Use a **Lock** to avoid race conditions.
- Each thread should increment the shared counter multiple times.
- Display the final value of the counter after all threads complete execution.

10: Design a Python application that creates two threads.

- Thread 1 should compute the **sum of elements** from a list.
- Thread 2 should compute the **product of elements** from the same list.
- Return the results to the main thread and display them.
